Estimation of Natural Groundwater Recharge (Nato Science Series C:)

In view of the rapidly expanding urban, industrial and agricultural water requirements in many areas and the normally associated critical unreliability of surface water supplies in arid and semi-arid zones, groundwater exploration and use is of fundamental importance for logical economic development. Two interrelated facets should be evident in all such groundwater projects : (a) definition of groundwater recharge mechanisms and characteristics for identified geological formations, in order to determine whether exploitation in the long-term involves 'mining' of an essentially 'fossil' resource or withdrawal from a dynamic supply. A solution to this aspect is essential for development of a resource management policy: (b) determination of recharge variability in time and space to thus enable determination of total aquifer input and to quantify such practical aspects as 'minimum risk' waste disposal locations and artificial recharge potential via (e.g.) revegetation or engineering works. However, current international developments relating to natural recharge indicate the following 'problems' ; no single comprehensive estimation technique can yet be identified from the spectrum of methods available; all are reported to give suspect results.
